Introduction

This guide outlines a consistent method for installing Ubuntu Server on a virtual machine for ABC Startup. Answers. It adheres to the specifications from the Week 3 project and is designed for novice system administrators.

Ubuntu Server Installation Guide

Create the VM using the required name, memory, CPU, storage, network, and Ubuntu Server ISO. Start the VM, choose English and the correct keyboard layout, accept DHCP, set hostname server01, create a non-root administrative account, use Guided – Use Entire Disk, enable OpenSSH Server, complete installation, reboot, and remove the ISO.

Initial Server Configuration

Hostname: server01

Network: DHCP

Remote administration: OpenSSH

Privileges: administrative non-root user

Storage: guided entire disk

Server Verification Procedures

Run hostname, ip addr, ping -c 4 google.com, sudo apt update, sudo apt upgrade -y, and systemctl status ssh. Capture evidence for every major verification step. SSH should report active (running).

Troubleshooting Guide

No network: check VM adapter/NAT and DHCP

SSH inactive: verify OpenSSH installation and service state.

Hostname mismatch: check hostname configuration.

Updates fail: test connectivity and retry package updates.

Low resources: confirm 4 GB RAM, 2 CPUs and 40 GB storage.

Best Practices

Utilize a non-root admin account rather than frequent root access. Utilize robust passwords. Ensure the server is current. Activate solely the necessary services. Document the server's hostname and IP address. Keep screenshots and setup notes for another administrator to replicate the installation. Employ SSH for safe remote access. management and confirm its operational status post-installation.
